## The relationship between the Chinese ‘going out’ strategy and international trade

*Ana Lucia Abeliansky and Inmaculada Martínez-Zarzoso*

### Abstract

This study is the first to estimate a system of simultaneous gravity equations for Chinese exports, imports and foreign direct investment (FDI) using a sample of 167 countries over the period 2003–2012. The main results indicate that trade and outward FDI are complementary. In particular, the authors show that outward Chinese FDI is related to higher exports and imports and that China trades more with countries hosting Chinese FDI. Results are also robust to the use of instrumental variables. Therefore, the popular claim that Chinese investment could be detrimental for developing countries is not supported by the data.

## 1. Introduction

During the late 1990s, China started its "going out" strategy with an intense program of outward foreign direct investment (FDI). According to UNCTAD statistics, Chinese outward FDI stock was about 33 billion USD in 2003, reaching almost 614 billion in 2013, which translates into a 30 percent annual growth rate. A timely question is whether this increase is related to Chinese exports and imports, in line with the idea that trade and FDI could be complements.

Recent investment agreements with China have raised concerns in the partner economies alleging that China's intention was to extract natural resources and could in turn force the host countries to re-orient their production to low value added products and extraction of natural resources (Economist, 2013). However, recent trade figures show that China has been increasingly investing in manufacturing activities and has gradually abandoned its focus on the extraction and mining sectors.

Meanwhile, given the close connections of the Chinese (business) community, it is to be expected that Chinese investment will generate an increase in demand –and in turn of imported products– mainly of intermediate inputs, high-tech goods and machinery needed to produce final manufacturing products in the host countries. Considering the deep connections between the Chinese ethnicity and business (Rauch and Trindade, 2002), Chinese exporters could profit from this increase in demand . Moreover, contrary to the traditional economic theory assuming that trade and FDI are substitutes (Mundell, 1957), Schmitz and Helmberger (1970), among others, have theoretically shown that trade and FDI could be complements under certain assumptions. Also the bulk of empirical evidence in regions worldwide points to the complementarity effects between FDI and exports (Brouwer et al. 2008; Egger, 2001; Chen et al. 2012; Cheung and Qian, 2009).

This paper departs from earlier literature in two main regards. Firstly, it investigates the trade-FDI link for the Chinese case in recent years, paying particular attention to the characteristics of the destination countries, to the presence of zeroes and to simultaneity issues. Secondly, it focuses on the effect of FDI not only on total exports, but also on Chinese imports. In particular, we estimate a gravity model of trade augmented with FDI and a model of FDI augmented with trade to investigate reverse causality issues. We consider exports and imports separately and test two main hypotheses. On the one hand, we hypothesize that China exports more to destinations where it is active in FDI. On the other hand, we expect that higher levels of FDI are associated with higher Chinese exports and imports.

The main results support both hypotheses. More specifically, we find that China exports 20 percent more to destinations in which it is active in FDI and, in the long run, higher FDI flows are associated to increases in exports.

The rest of the paper is structured as follows. Section presents a review of the closely related literature. Section 3 describes the data and presents some stylized facts. Section 4 specifies the model, shows and discusses the main results and presents some robustness checks. Finally Section 5 concludes.

## **2. Trade and FDI in the gravity model**

Gravity models have been considered the workhorse of international trade in the recent decades and are a widely accepted empirical tool (Head and Mayer, 2014). These models have also been used to estimate the determinants of bilateral FDI and some authors estimate FDI and trade models simultaneously. In particular, Brouwer et al (2008) estimated gravity models of trade and FDI separately for a sample of 28 European countries over the period 1990 to 2004 and find a positive and significant correlation between bilateral FDI and bilateral trade, when FDI is included as explanatory variable in the gravity model of trade. However, the authors do not tackle the problems

related to missing data in FDI (around 50 percent), endogeneity of the FDI variable or reverse causality. In contrast to these authors, Egger (2001) estimated a system of simultaneous equations for trade and FDI using intra-EU bilateral flows from 1988 to 1996, allowing for the endogeneity of both exports and FDI variables in the system. He finds that, in line with the theoretical models of Helpman (1984) and Markusen and Maskus (1999), bilateral exports are an increasing function of outward FDI stocks. However, the effect is only statistically significant in the long run.

Chen et al (2012) analyzed the relationship between outward FDI and exports of 15 Taiwanese manufacturing industries over the period from 1991 to 2007. The main results, obtained using random and fixed effects estimators, show the existence of complementarity between FDI and exports. Most of the abovementioned studies use lagged FDI values to control for the endogeneity of FDI in the trade equation, whereas lagged exports are used in the FDI equation. The reverse causality issue is also considered in Cheung and Qian (2009) who analyze the effect of Chinese exports as a determinant of Chinese outward FDI also using the lagged value of exports to mitigate the endogeneity problem. They find that this relationship is positive and gets stronger when the host economies are developing countries. Also focusing on China, Caporale et al (2015) analyzed China's trade with North America, Asia and Europe and its relationship with inward FDI. They found a positive relationship, stronger for the period after China joined the WTO. Their main concern is the endogeneity due to time-invariant variables, but they fail to account for the reverse causality problem that could arise by the inclusion of FDI in this setting. We differ from this study given that we focus on the outward FDI and how it correlates with exports, and imports, plus employing econometric methods that aim to consider the correlation of the determinants of the different variables, and simultaneity issues. Moreover, we include all available countries for which there is data, regardless of the continent they belong to. A second paper focused on China's trade is Yang and Martinez-Zarzoso (2014), which assessed the effect of the ASEAN-China trade agreement on sectoral trade. The authors found mainly net trade creation effects, but did not considered FDI as a control variable in their gravity model focusing exclusively on trade flows.

Some recent studies use firm level data to investigate the relationship between FDI and trade in Africa. In particular, Broadman (2007) using firm level data World Bank Africa Asia Trade Investment (WBAATI) survey and the World Bank's newly developed business case studies of Chinese firms in Africa, find that there are positive links between FDI and trade among Chinese firms involved in Africa. In particular, the attraction of investment for infrastructure and related services development seems to create "spillovers" on the continent. Moreover intangible assets, such as technology transfer and transfer of managerial skills, which usually accompany FDI, also act as vehicles stimulating trade. Similar evidence is shown in Chen and Tang (2014). Applying propensity score matching techniques to compare firms that have similar characteristics ex-ante, the authors show that Chinese firms engaged in outward FDI export 0.6 log points more than firms that do not invest abroad. These results show that horizontal FDI from China complements firms' trade, consistent with the idea that exporting entails high fixed costs and that FDI helps reduce those fixed costs.

### **3. Data and Stylized Facts**

We use bilateral FDI data from UNCTAD, trade data from COMTRADE and gravity variables, namely distance between the capital cities (lnDist), colonial relationship (Colony), common legal origin (Comleg), and common language that is spoken by at least 9% of the population (Comlang) from CEPII. GDPs and population are from the WDI, while the regional trade agreement (RTA) dummy is from De Sousa (2012)<sup>1</sup>. The bilateral investment treaty dummy variable (BIT) is created with information obtained from UNCTAD. We use BIT ratification instead of BIT signature since the relevant date is the one in which the agreement enters into force; the same applies for the RTA variable. The sample includes 167 partner countries and cover the years from 2003 to 2012. Summary statistics for all the variables included in the analysis are shown in Table 1.

---

**Table 1. Summary Statistics**

Variable	mean	p50	sd	min	max	N
Ln Exports	20.195	20.269	2.418	11.992	26.588	1648
Ln Imports	18.593	18.955	9.969	0	25.994	1648
Ln GDP	24.048	23.812	2.293	18.434	30.414	1648
Ln Population	15.782	15.920	1.849	9.905	20.936	1648
Ln Distance	9.031	9.076	0.493	7.063	9.858	1648
Ln FDI Stock	3.769	3.898	2.221	-0.693	9.746	1262
RTA	0.055	0	0.228	0	1	1648
Common Colony	0.006	0	0.077	0	1	1648
Common Legal System	0.176	0	0.381	0	1	1648
Common Language	0.012	0	0.110	0	1	1648
BIT	0.556	1	0.497	0	1	1648

Note: RTA denotes regional trade agreement and BIT bilateral investment agreement.

Graphical inspection of the data shows that Chinese exports are significantly higher in destinations where China is also engaged in FDI (Figure 1) and Chinese outward FDI is positively correlated with Chinese exports (Figure 2), the same applies to imports (Figure 3 and Figure 4).

#### 4. Model specification and estimation results

##### 4.1 Model Specification

We estimate a system of seemingly-unrelated gravity equations in which FDI, exports and imports are the endogenous variables and enter with one lag as explanatory variables. The model is specified as follows:

$$\ln X_{jt} = \alpha_0 + \alpha_1 \ln(\max\{1, FDI_{jt-1}\}) + \alpha_2 \text{NFDI}_{jt} + \alpha_3 \ln M_{jt-1} + \alpha_4 \ln GDP_{jt} + \alpha_5 \ln Pop_{jt} + \alpha_6 \ln Dist_{jt} + \alpha_7 \text{Colony}_j + \alpha_8 \text{Comleg}_j + \alpha_9 \text{Comlang}_j + \alpha_{10} \text{RTA}_{jt} + \sum_{t=1}^{T-1} \delta_t + \sum_{i=1}^{I-1} \rho_i + u_{jt} \quad (1)$$

$$\ln M_{jt} = \beta_0 + \beta_1 \ln(\max\{1, FDI_{jt-1}\}) + \beta_2 \text{NFDI}_{jt} + \beta_3 \ln X_{jt-1} + \beta_4 \ln GDP_{jt} + \beta_5 \ln Pop_{jt} + \beta_6 \ln Dist_{jt} + \beta_7 \text{Colony}_j + \beta_8 \text{Comleg}_j + \beta_9 \text{RTA}_{jt} + \beta_{10} \text{Comlang}_j + \sum_{t=1}^{T-1} \theta_t + \sum_{i=1}^{I-1} \vartheta_i + \mu_{jt} \quad (2)$$

$$\ln(\max\{1, FDI_{jt}\}) = \gamma_0 + \gamma_1 \ln X_{jt-1} + \gamma_2 \ln M_{jt-1} + \gamma_3 \ln GDP_{jt} + \gamma_4 \ln Pop_{jt} + \gamma_5 \ln Dist_{jt} + \gamma_6 \text{Colony}_j + \gamma_7 \text{Comleg}_j + \gamma_8 \text{Comlang}_j + \gamma_9 \text{BIT}_{jt} + \sum_{t=1}^{T-1} \pi_t + \sum_{i=1}^{I-1} \varphi_i + v_{jt} \quad (3)$$

where  $j$  denotes the partner country and  $t$  the year.  $\delta_t$ ,  $\theta_t$  and  $\pi_t$  are time dummies, while  $\rho_i$ ,  $\vartheta_i$  and  $\varphi_i$  are regional dummies. Regional dummies account for multilateral resistance factors and the time dummies account for common trends in Chinese exports, imports and FDI. Given the existence of

zeros in the FDI variable, we follow Martinez-Zarzoso et al. (2017) and Wagner (2003) and create a dummy to account for the absence of FDI and another variable to measure the impact of the level of the observed FDI. The effect of FDI is then specified in the following way:

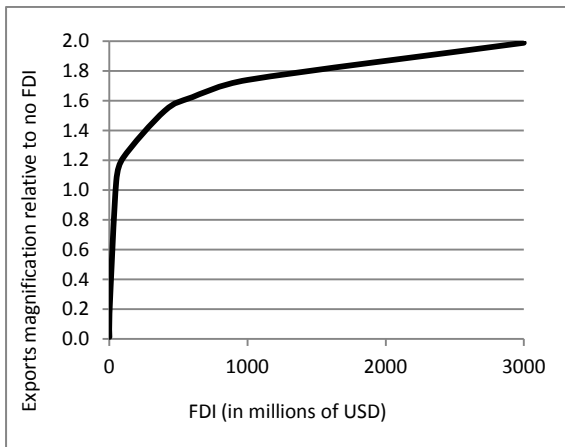

$$\alpha_1 \ln(\max\{1, FDI_{jt}\}) + \alpha_2 \text{NFDI}_{jt} = \begin{cases} \alpha_1 \ln FDI_{j,t} & \text{when } FDI_{j,t} > 0 \\ \alpha_2 & \text{when } FDI_{j,t} = 0 \end{cases} \quad (4)$$

Thus,  $\alpha_1(\beta_1)$  measures the elasticity where FDI is positive and  $\alpha_2(\beta_2)$  modifies the constant term when FDI is zero.  $FDI_{j,t-1}$  denotes the lagged value of outward Chinese FDI stock in country j and period t-1 and NFDI is a dummy variable that takes the value of one when the FDI stock is zero in country j and time t. *4.2 Main Results*

The main results using equations (1)-(3) are shown in Table 2. Column 1 reports the results for exports (eq.1), column 2 for imports (eq.2) and column 3 for FDI (eq. 3). We observe a positive and statistically significant effect of FDI on exports and imports. For instance, increasing FDI to a host country by 10 percent, increases Chinese exports by 2.27 percent and imports by 1.38 percent (column 1, Table 2). We can use this elasticity to calculate how much export (imports) should increase per dollar of FDI according to our results. Each dollar of additional FDI on average yields an additional USD 4.4 of exports (USD 2.32 of imports). The results in column 3 indicate that increases in the volume of exports and imports also foster Chinese FDI outflows significantly.

Concerning the no-FDI dummy (NFDI), the coefficient, which is -0.17 in column 1 (-0.45 in column 2), should be interpreted as follows. Logged exports (imports) when FDI is positive exceed logged exports (imports) when FDI is zero by  $0.227 * \ln FDI + 0.172$  ( $0.138 * \ln FDI + 0.450$ ). In Figure 5 and Figure 6 we can observe the "excess" of log exports or imports, for the amount invested, compared to a scenario of no investment. For smaller amounts of FDI, the presence of FDI generates higher "excess returns" for imports than for exports, but the situation is the opposite for investments above 22.7 millions of USD.

**Figure 5. FDI and Exports**

**Figure 6. FDI and Imports**

As regards the control variables, the coefficient of the GDP of China's trading partners is positive and statistically significant, in the export and import equations (columns 1 and 2) as the gravity model predicts. The population coefficient is positive for Chinese exports and FDI and negative for imports, indicating that the size of the destination market is associated to higher exports and more FDI but with a reduction of Chinese imports. Among the time-invariant gravity variables, colony, sharing a common legal origin and sharing a common language show the expected positive effect on imports and FDI, but the effect is not always statistically significant, e.g. in the export eq. for the former two variables. It is interesting to notice that Chinese exports are explained mainly by market size variables (GDP and population) and common language of ethnic groups, while imports are more sensitive to historical and cultural links (colonial relationship and sharing a common legal origin) and

regional trade agreements. Distance has an unexpected positive effect on imports, which indicates that imports are higher from far away destinations, perhaps indicating that the continental dummies do not fully capture multilateral resistance factors.

Concerning the RTA dummy, it indicates that entering into trade agreements promotes Chinese imports in the period considered. Finally, the BIT dummy in equation (3) has a positive and significant coefficient indicating that China invests around 50 percent more in host countries with whom it has signed a BIT than in non-signatory countries.

**Table 2. Results with Seemingly Unrelated Regressions**

	(1) Ln Exports	(2) Ln Imports	(3) Ln (max{1, FDI <sub>jt</sub> })

Comleg <sub>j</sub>	-0.044 (0.087)	0.755*** (0.172)	0.408*** (0.153)
Common Language <sub>j</sub>	0.844*** (0.237)	0.287 (0.481)	0.804** (0.393)
BIT			0.407*** (0.115)
Observations	1,471	1,471	1,471
R-squared	0.844	0.771	0.596
Year Dummies	YES	YES	YES
Continent Dummies	YES	YES	YES

Note: Standard errors in parentheses. \*\*\* p<0.01, \*\* p<0.05, \* p<0.1. The default for the continental dummies is Africa.

In Table 3 we can see the correlation matrix of the residuals. Since the null hypothesis of no correlation among the residuals is rejected, the SUR methodology improves the estimation over the Ordinary Least Squares.

**Table 3. Correlation Matrix of Residuals**

	Ln Exports	Ln Imports	Ln FDI
Ln Exports	1		
Ln Imports	-0.109	1	
Ln FDI	-2.201	-0.1	1

Breusch-Pagan test of independence:  $\chi^2(3) = 103.117$ ,  $Pr = 0.000$

Summarising, the main results show that both hypotheses are confirmed. China exports less to (import less from) destinations with zero FDI, and an increase of 10 percent in FDI stocks increases exports by 2.3 percent (imports by 1.4 percent).

#### 4.3. Robustness

As a robustness test, we estimate independently each equation (outward FDI, exports and imports) and instrument the two variables that are potentially endogenous (as instruments in each specification we use the corresponding variable lagged two periods). The Hansen test statistics (see last row of Table 4) indicate that the instruments are valid. Moreover, we estimated a Dynamic OLS model and the results also corroborate the main findings obtained in the paper<sup>2</sup>.

---

<sup>2</sup> Results are available upon request. Unfortunately, given the short time span of the data, unit root tests could not be conducted. Hence, the results from these models should be interpreted with caution.

Finally, we estimated the model using a between estimator and the main results are shown in Table 5. Some authors argue that the estimated elasticities could be interpreted as long-run effects (Stern, 2010). Basically, the model is estimated for the time-averages of the variables and it does not make a priori assumptions concerning the nature of the time effects. Hence, in real world data situations, with this estimator we are likely to obtain estimates that are robust to misspecification of dynamics.

The first part of Table 5 shows the results obtained when the three equations (for exports imports and FDI) are considered independent, whereas the second part shows the results when we allow for unrestricted correlation between the error terms of the three equations (BE-SUR). The main results indicate that higher Chinese FDI induces higher exports from China in the long-run (column1, Table 5), and the same can be said with respect with higher exports inducing higher outward FDI (column 3, Table 5). However, the coefficient of lagged imports (exports) is not statistically significant in column 1 (column 2), but turns significant and positive when accounting for the correlation across error terms in column 4 (column 5). Results in column 6 also confirm that higher imports (exports) from China attract more FDI from the same country (column 4) in the long-run. The estimated coefficients are higher in magnitude when the BE-SUR estimator is used, indicating a downward bias in the estimations shown in the first part of Table 5.

The default for the continental dummies is Africa.

## 5. Conclusions

In the 2000s, China has been actively investing abroad, becoming the third largest investor in the world. Many have challenged the benefits of the Chinese investments in the local economies. Using a system of seemingly unrelated gravity equations for exports, imports and FDI we show that FDI appears to be complementary to Chinese exports and imports. These results are also robust to an instrumental variable approach. Chinese FDI is not that bad after all - despite being correlated to higher imports from China, it is also associated to higher exports to China. Future work entails the analysis of different product groups to investigate the potential heterogeneity of the relationships.

## Appendix

Table 5. List of Countries

Afghanistan	Canada	Gambia	Kuwait	Niger	Sri Lanka
Albania	Cape Verde	Georgia	Kyrgyzstan	Nigeria	Suriname
Algeria	Central African Republic	Germany	Laos	Norway	Swaziland
Angola	Chad	Ghana	Latvia	Oman	Sweden
Antigua and Barbuda	Chile	Greece	Lebanon	Pakistan	Switzerland
Argentina	Colombia	Grenada	Lesotho	Palau	Tajikistan
Armenia	Comoros	Guatemala	Liberia	Panama	Tanzania
Australia	Congo	Guinea	Libya	Papua New Guinea	Thailand
Austria	Congo, Democratic Republic	Guinea-Bissau	Lithuania	Paraguay	Togo
Azerbaijan	Costa Rica	Guyana	Luxembourg	Peru	Tonga
Bahamas	Croatia	Haiti	Madagascar	Philippines	Trinidad and Tobago
Bahrain	Cyprus	Honduras	Malawi	Poland	Tunisia
Bangladesh	Czech Republic	Hungary	Malaysia	Portugal	Turkey
Belarus	Denmark	Iceland	Maldives	Qatar	Turkmenistan
Belgium	Djibouti	India	Mali	Romania	Uganda
Belize	Dominica	Indonesia	Malta	Russian Federation	Ukraine
Benin	Dominican Republic	Iran	Mauritania	Rwanda	United Arab Emirates
Bhutan	Ecuador	Ireland	Mauritius	Samoa	United Kingdom
Bolivia	Egypt	Israel	Mexico	Sao Tome and Principe	United States
Bosnia and Herzegovina	El Salvador	Italy	Moldova	Saudi Arabia	Uruguay
Botswana	Equatorial Guinea	Ivory Coast	Mongolia	Senegal	Uzbekistan
Brazil	Eritrea	Jamaica	Morocco	Seychelles	Vanuatu
Brunei	Estonia	Japan	Mozambique	Sierra Leone	Venezuela
Bulgaria	Ethiopia	Jordan	Namibia	Singapore	Vietnam
Burkina	Fiji	Kazakhstan	Nepal	Slovakia	Yemen
Burundi	Finland	Kenya	Netherlands	Slovenia	Zambia
Cambodia	France	Kiribati	New Zealand	South Africa	Zimbabwe
Cameroon	Gabon	Korea, South	Nicaragua	Spain
